

Obesity in Cats

In North America, obesity is the most common *preventable* disease in cats. Approximately 25–35% of the general feline population is obese, with 40–45% of cats aged 5–11 years old weighing in higher than normal.

What is obesity?

Obesity is an accumulation of excess body fat. Extra body weight and extra body fat tend to go hand in hand, so most overweight cats will have excess body fat.

What are the risks with obesity?

Excess fat negatively impacts a cat's health and longevity. Even being moderately overweight reduces feline life expectancy. While the same study does not yet exist for cats, we have very compelling data that links excess weight and decreased life expectancy in dogs.

A large, lifetime study of Labrador retrievers found that a moderately overweight group of dogs lived nearly two years less than their leaner counterparts. It's a sobering statistic as it was always accepted that heavy dogs lived a shorter time than lean dogs, but by only 6–12 months. It's reasonable to expect we would see similar results in a study performed on overweight cats.

Previously, fat was considered to be relatively inert tissue, simply storing excess energy calories and adding to body mass. Scientific evidence now reveals that fat tissue is biologically active, however. It secretes inflammatory hormones and creates oxidative stress on the body's tissue, both of which contribute to many diseases. Thinking of obesity as a chronic, low-level inflammatory condition is a new paradigm.

"Excess fat negatively impacts a cat's health and longevity."

Obese cats develop an increased risk for:

- cancers of all types, diabetes mellitus, heart disease and hypertension,
- osteoarthritis and a faster degeneration of affected joints,
- urinary bladder stones, and
- anesthetic complications as they're less heat tolerant.

Obese cats who stop eating are at great risk for developing a potentially life-threatening condition called hepatic lipidosis – a devastating upset of normal liver function. Other potential complications of obesity in cats include skin problems and reduced immune system function.

How do I know if my cat is obese?

The very first step in dealing with an overweight or obese cat is to recognize and acknowledge that there is a problem. Unfortunately, we are inundated with images in the media of cats that are consistently too heavy, which makes it challenging to understand what *normal* looks like. Your veterinarian and the veterinary health care team can assist with an assessment.

Rib coverage is not only an important measurement to help you identify if your cat is overweight, but it's also easy for you to do at home, on your own. If you hold your hand palm down and feel your knuckles with the flats of the fingers on the opposite hand, this is how your cat's ribs should feel just behind the shoulder blades. It's also a good method for measuring weight loss progress between formal weigh-ins.

Your veterinary health care team will provide an estimated ideal body weight to use as a target, but it is important that they also do regular body condition assessments to ensure progress is being made toward normal body weight and body condition. Most veterinary practices use a body condition scoring system on a scale of either 1–5 (3 is normal) or 1–9 (4.5 is normal).

"Rib coverage is not only an important measurement to help you identify if your cat is overweight, but it's also easy for you to do at home, on your own."

How do I adjust my cat's meals to help him lose weight?

Once you've identified that your cat is overweight or obese, it is important to adjust feedings specifically for weight loss – using a specific nutritional product, a specific portion and a specific meal frequency. There are scientifically formulated nutritional products to help with healthy and safe weight reduction in cats.

It *is* appropriate and important to feed a nutritional product that has lower overall calorie density, yet maintains an appropriate nutrient balance. The veterinary health care team can help you determine which nutritional products are best for your cat.

Once the new food has been selected and the new portions are determined, it is critical that you be consistent with feeding – portions and meal frequency – and to resist the temptation to provide inappropriate snacks.

What happens when we reach our weight loss goal?

Once an ideal body weight and condition has been achieved, it is important to maintain. Once again, the veterinary health care team can help you find an appropriate food and portion for weight maintenance.

Portion control is critical at this stage to prevent regaining weight. After so much hard work, a relapse in obesity would be unfortunate. Yo-yo weight loss and gain is no healthier for cats than for humans. The benefits of normalizing body weight and condition make the effort well worth it!
